Define the following functions:

```python
def mystery1(x):
    return x * 2 + 5

def mystery2(x):
    return x ** 2 - 3

def mystery3(x):
    return (x + 7) / 2

def mystery4(x):
    return x * x * x - x

def mystery5(x):
    return (x - 1) * (x + 1)

def mystery6(x):
    return x % 5 + 10
```

For function `mystery4`, what is that function's **argument**?

What does it mean to **call a function**?

Trace the following snippets using the functions:

Python

```
x = 2
y = 5
x = mystery1(x)
y = mystery3(y)
x = y - x
print(x, y)
```

Python

```
p = 1
q = 6
temp = p
p = mystery5(q)
q = mystery1(temp)
print(p, q)
```

Python

```
v = 10
v = mystery3(mystery1(v))
print(v)
```

Python

```
total = 0
total = mystery1(total)
total = mystery1(total)
total = mystery6(total)
print(total)
```

Python

```
a = 2
b = 3
a = mystery2(a)
b = mystery4(b)
a = a + b
b = mystery5(a)
print(a, b)
```
